Program Structures and Algorithms

Spring 2023(SEC –1)

NAME: Foram Kamani

NUID: 002732551

Task:

Your task is to implement a parallel sorting algorithm such that each partition of the array is sorted in parallel. You will consider two different schemes for deciding whether to sort in parallel.

1. A cutoff (defaults to, say, 1000) which you will update according to the first argument in the command line when running. It is your job to experiment and come up with good value for this cutoff. If there are fewer elements to sort than the cutoff, then you should use the system sort instead.
2. Recursion depth or the number of available threads. Using this determination, you might decide on an ideal number (*t*) of separate threads (stick to powers of 2) and arrange for that number of partitions to be parallelized (by preventing recursion after the depth of *lg t* is reached).
3. An appropriate combination of these.

Relationship Conclusion:

As per performing analysis on varied sizes of arrays for several different threads ranging from 2 to 64, we can determine that the runtime increases as the array size grows, regardless of the thread and cut-off values. However, after a certain cutoff value, adding more threads has no impact on performance, as evidenced by the similar runtimes for thread values. Moreover, the depth will never exceed the maximum depth since the array has reached the cutoff at any given time.

The following conclusion was drawn for the thread count (T) and recursion depth (d):

$T = 2^d$

Graphical Representation:

Array Size = 2000000

Cutoff Ratio: cutoff/size of Array

Array Size = 2000000
